A. Automorphism

First, can we solve the problem for a rooted tree?

The general idea resembles the algorithm for checking rooted trees isomorphism.

We would like to assign a number to each subtree in such a way that subtrees are isomorphic iff their numbers are equal.

This can be done as follows: recursively assign a number to each of the child's subtrees, then sort all the obtained numbers. Call the resulting vector a *profile* of the subtree.

A. Automorphism

First, can we solve the problem for a rooted tree?

The general idea resembles the algorithm for checking rooted trees isomorphism.

We would like to assign a number to each subtree in such a way that subtrees are isomorphic iff their numbers are equal.

This can be done as follows: recursively assign a number to each of the child's subtrees, then sort all the obtained numbers. Call the resulting vector a *profile* of the subtree.

Note that different profiles correspond to non-isomorphic trees, and vice versa.

A. Automorphism

First, can we solve the problem for a rooted tree?

The general idea resembles the algorithm for checking rooted trees isomorphism.

We would like to assign a number to each subtree in such a way that subtrees are isomorphic iff their numbers are equal.

This can be done as follows: recursively assign a number to each of the child's subtrees, then sort all the obtained numbers. Call the resulting vector a *profile* of the subtree.

Note that different profiles correspond to non-isomorphic trees, and vice versa.

Store a global list of different profiles, with the mapping from profiles to unique numbers. If the current profile was not met before, assign it a new number and remember the profile.

A. Automorphism

How to deal with general (unrooted) trees?

Definition

A vertex v is called a *centroid* of the tree if all its subtrees contain at most $n/2$ vertices.

A. Automorphism

How to deal with general (unrooted) trees?

Definition

A vertex v is called a *centroid* of the tree if all its subtrees contain at most $n/2$ vertices.

Fact

A tree may only contain a unique centroid, or a pair of adjacent centroids.

A. Automorphism

How to deal with general (unrooted) trees?

Definition

A vertex v is called a *centroid* of the tree if all its subtrees contain at most $n/2$ vertices.

Fact

A tree may only contain a unique centroid, or a pair of adjacent centroids.

Observation

Any automorphism maps a centroid to a centroid (possibly the same).

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.
- If there are two centroids, they may stay in their places, or swap their positions.

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.
- If there are two centroids, they may stay in their places, or swap their positions.
If their subtrees (obtained by removing the edge connecting the centroids) are non-isomorphic, then the centroids stay in their places, and each one is associated with the rooted tree problem.

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.
- If there are two centroids, they may stay in their places, or swap their positions.

If their subtrees (obtained by removing the edge connecting the centroids) are non-isomorphic, then the centroids stay in their places, and each one is associated with the rooted tree problem.

Otherwise, the centroids may be swapped. As their subtrees are isomorphic, the total answer is $2x^2$, where x is the answer for a subtree of a single centroid.

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.
- If there are two centroids, they may stay in their places, or swap their positions.

If their subtrees (obtained by removing the edge connecting the centroids) are non-isomorphic, then the centroids stay in their places, and each one is associated with the rooted tree problem.

Otherwise, the centroids may be swapped. As their subtrees are isomorphic, the total answer is $2x^2$, where x is the answer for a subtree of a single centroid.

The complexity is still $O(n \log n)$.

A. Automorphism

- If the tree contains a unique centroid, then it is a fixed point of any automorphism, and the problem is reduced to the rooted tree problem.
- If there are two centroids, they may stay in their places, or swap their positions.

If their subtrees (obtained by removing the edge connecting the centroids) are non-isomorphic, then the centroids stay in their places, and each one is associated with the rooted tree problem.

Otherwise, the centroids may be swapped. As their subtrees are isomorphic, the total answer is $2x^2$, where x is the answer for a subtree of a single centroid.

The complexity is still $O(n \log n)$.

Note that assigning unique numbers to non-isomorphic trees can be done in linear time (without hashing).

B. Laser Billiards

We have to count each intersection once, even when we collide with two beams at one moment.

If we should have counted such moments twice, the problem would be independent for vertical and horizontal beams collision.

B. Laser Billiards

We have to count each intersection once, even when we collide with two beams at one moment.

If we should have counted such moments twice, the problem would be independent for vertical and horizontal beams collision.

The problem for one type of beams is fairly easy: for, say, vertical beams we can use reflection principle over vertical edges to obtain a periodical infinite sequence of strips. After that, counting reduces to range queries on the periodical array.

B. Laser Billiards

It suffices to count double collisions along the path.

B. Laser Billiards

It suffices to count double collisions along the path.
 We can count the number of segments lying on the path using the reflection principle.

B. Laser Billiards

It suffices to count double collisions along the path.

We can count the number of segments lying on the path using the reflection principle.

As the number of segments can be large, we should use faster summation methods. For example, count the DP “total number of double collisions starting at current segment and following 2^k segments forward” to sum along path of length l in $O(\log l)$ time.

B. Laser Billiards

It suffices to count double collisions along the path.

We can count the number of segments lying on the path using the reflection principle.

As the number of segments can be large, we should use faster summation methods. For example, count the DP “total number of double collisions starting at current segment and following 2^k segments forward” to sum along path of length l in $O(\log l)$ time. It suffices to account for proper parts of start and finish segments. This can be done using bitmasks in $\sim ((n + m)/32)$ time.

$$\text{Prob}(L(X, Y, t), H(x, y, t), H(x_1, y_1, t_1), \dots) =$$

$$\text{Prob}(L(X, Y, t), H(x_1, y_1, t_1), \dots) \cdot$$

$$\text{Prob}(H(x, y, t) | L(X, Y, t), H(x_1, y_1, t_1), \dots)$$

C. SmartDog

$$\text{Prob}(L(X, Y, t), H(x, y, t), H(x_1, y_1, t_1), \dots) =$$

$$\text{Prob}(L(X, Y, t), H(x_1, y_1, t_1), \dots) \cdot$$

$$\text{Prob}(H(x, y, t) | L(X, Y, t), H(x_1, y_1, t_1), \dots)$$

$$p(X, Y) \text{Prob}(H(x_1, y_1, t_1), \dots) \cdot \text{Prob}(H(x, y, t) | L(X, Y, t))$$

C. SmartDog

$$\text{Prob}(L(X, Y, t), H(x, y, t), H(x_1, y_1, t_1), \dots) =$$

$$\text{Prob}(L(X, Y, t), H(x_1, y_1, t_1), \dots) \cdot$$

$$\text{Prob}(H(x, y, t) | L(X, Y, t), H(x_1, y_1, t_1), \dots)$$

$$p(X, Y) \text{Prob}(H(x_1, y_1, t_1), \dots) \cdot \text{Prob}(H(x, y, t) | L(X, Y, t))$$

Again, $\text{Prob}(H(x_1, y_1, t_1), \dots)$ can be omitted.

C. SmartDog

$$\text{Prob}(L(X, Y, t), H(x, y, t), H(x_1, y_1, t_1), \dots) =$$

$$\text{Prob}(L(X, Y, t), H(x_1, y_1, t_1), \dots) \cdot$$

$$\text{Prob}(H(x, y, t) | L(X, Y, t), H(x_1, y_1, t_1), \dots)$$

$$p(X, Y) \text{Prob}(H(x_1, y_1, t_1), \dots) \cdot \text{Prob}(H(x, y, t) | L(X, Y, t))$$

Again, $\text{Prob}(H(x_1, y_1, t_1), \dots)$ can be omitted.

$\text{Prob}(H(x, y, t) | L(X, Y, t))$ is by definition

$$N e^{-((x-X)^2 + (y-Y)^2) / 2\sigma^2}.$$

C. SmartDog

$$\text{Prob}(L(X, Y, t), H(x, y, t), H(x_1, y_1, t_1), \dots) =$$

$$\text{Prob}(L(X, Y, t), H(x_1, y_1, t_1), \dots) \cdot$$

$$\text{Prob}(H(x, y, t) | L(X, Y, t), H(x_1, y_1, t_1), \dots)$$

$$p(X, Y) \text{Prob}(H(x_1, y_1, t_1), \dots) \cdot \text{Prob}(H(x, y, t) | L(X, Y, t))$$

Again, $\text{Prob}(H(x_1, y_1, t_1), \dots)$ can be omitted.

$\text{Prob}(H(x, y, t) | L(X, Y, t))$ is by definition

$$Ne^{-((x-X)^2 + (y-Y)^2) / 2\sigma^2}.$$

To sum up, $p'(X, Y)$ is just $p(x, y)$ multiplied by probability of hearing noise at (x, y) if the cat is at (X, Y) (which makes sense).

D. Expression

Given an arithmetic expression, erase as much bracket pairs as possible so that the expression keeps its original meaning.

More specifically, we can assume that multiplication/division has higher priority than addition/subtraction, and addition and multiplication are associative. Also, subtraction can be combined with addition if it is a second operation, and similarly division can be combined with multiplication.

No more assumptions can be made about the operations.

There are several cases to consider.

- If the expression inside of brackets is a letter, then the brackets can be removed indefinitely.
- If the expression inside of brackets is a product (according to the described context-free grammar), the brackets can be removed iff there is no division ($/$) immediately before the term t .

D. Expression

Consider a term t of the form (expression). We assume that all brackets inside the term have been removed when possible.

There is a unique maximal (unextendable) product containing the term, and unique maximal expression containing the product as an operand of $+$ or $-$.

There are several cases to consider.

- If the expression inside of brackets is a letter, then the brackets can be removed indefinitely.
- If the expression inside of brackets is a product (according to the described context-free grammar), the brackets can be removed iff there is no division ($/$) immediately before the term t .
- Otherwise, the brackets can be removed if the term t is not a proper part of the product (that is, does not take part in the multiplication or division immediately), and also there is no $-$ immediately before the term t .

J. Triangle

One possible approach is to apply Euclidean-like algorithm.

J. Triangle

One possible approach is to apply Euclidean-like algorithm.
 We assume that $GCD(a, b) = 1$, otherwise we can divide A , B and C by $GCD(A, B)$ (with rounding down). Also assume that $A \leq B$ and $C \geq 0$.

J. Triangle

One possible approach is to apply Euclidean-like algorithm.
 We assume that $GCD(a, b) = 1$, otherwise we can divide A, B and C by $GCD(A, B)$ (with rounding down). Also assume that $A \leq B$ and $C \geq 0$.

Consider region $ax + by \leq c, x, y \geq 0$.

J. Triangle

Denote $y_0 = \lfloor \frac{C}{B} \rfloor$, $x_0 = \lfloor \frac{C - By_0}{A} \rfloor$. Point (x_0, y_0) is the rightmost of the top points inside the region.

J. Triangle

Denote $y_0 = \lfloor \frac{C}{B} \rfloor$, $x_0 = \lfloor \frac{C - By_0}{A} \rfloor$. Point (x_0, y_0) is the rightmost of the top points inside the region.

Let $k = \lfloor \frac{B}{A} \rfloor$. The orthogonal trapezoid with top-right point (x_0, y_0) and right side along the vector $(k, -1)$ is inside the region.

J. Triangle

Apply coordinate transformation $x \rightarrow x - k \cdot (y_0 - y) - x_0 - 1$. This transformation takes the points inside the trapezoid to points with negative x , the number of such points can be counted explicitly.

J. Triangle

Apply coordinate transformation $x \rightarrow x - k \cdot (y_0 - y) - x_0 - 1$. This transformation takes the points inside the trapezoid to points with negative x , the number of such points can be counted explicitly. The rest is a region $a'x + b'y \leq c'$, where $b' = b$, $a' = b - ka$. Count the number of points in this region recursively.

J. Triangle

Since we're basically applying Euclid's algorithm to A and B , the number of iterations, and thus the total complexity will be $O(\log(a + b))$.
