

# BAPC Preliminaries 2012

---

STATS + SOLUTIONS + SCORES

# SUBMISSIONS OVER TIME

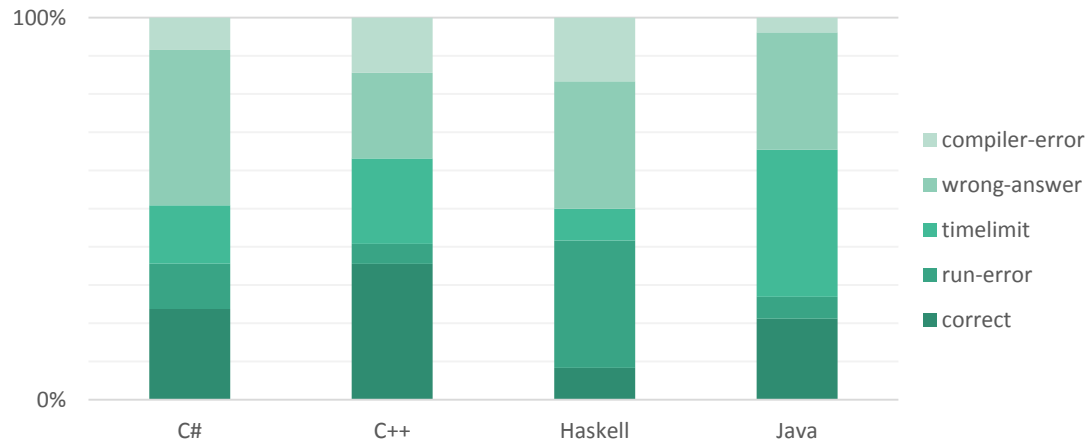

\* STATS FROM UTRECHT + TWENTE

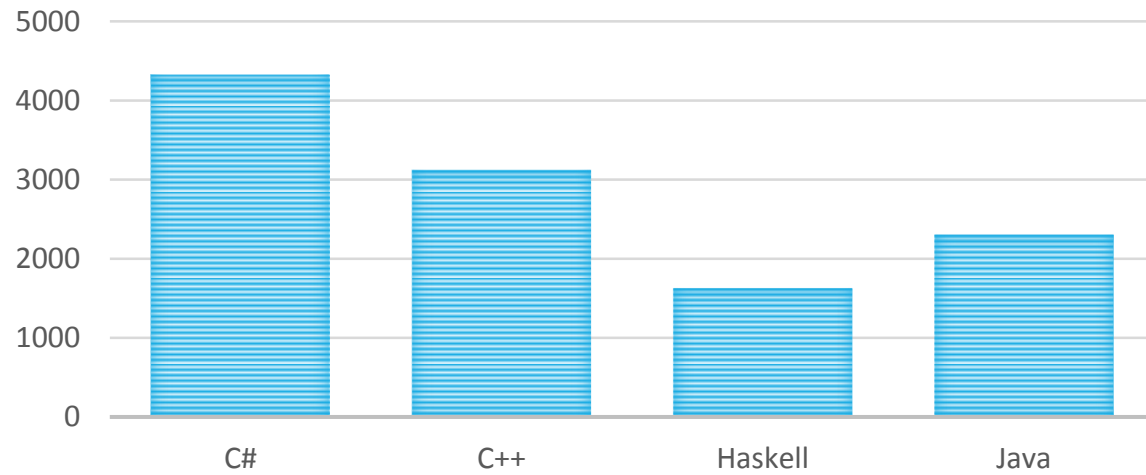

## SUBMISSIONS BY LANGUAGE

## SUBMISSIONS BY LANGUAGE

## AVERAGE CODE LENGTH

# Solutions

---

# Annoying Mosquitos

---

Don't be tempted to loop through all gridpoints in a swat

For each swat, check which mosquitos are in range

- Don't bother with quadtrees, this is fast enough

$O(nm)$

# Hex

Twice a **Depth First Search** or **Breadth First Search**

$$O(n^2)$$

# Cubing

---

## *Just simulate*

- But tricky to get all cases correct!

## Possible strategies

- Represent the moves by a combination of a few (3) basic moves
- Don't explicitly program all the changing variables but represent them in an easily readable format (like string) and interpret that
- Geometric approach where every sticker is a point in 3d space

$O(n)$

# Jumbled Letters

---

**Normalize** words for quick lookup

- For example by sorting the letters

Store all words in map (like **HashMap**) with normalized word as key

**For each subset** of the letters check if normalized version is present in map

Output the longest/alphabetically first

$O(2^k c)$  lookups (where  $k$  = the number of letters)

# Float to Fraction

---

$$\begin{aligned} 0.abcd(ef) &= 0.abcd + 0.0000(ef) \\ &= \frac{abcd}{10000} + \frac{0.(ef)}{10000} \end{aligned}$$

$$\begin{aligned} 0.(ef) \times 100 - 0.(ef) &= ef \\ 0.(ef) \times 99 &= ef \\ 0.(ef) &= ef/99 \end{aligned}$$

⏟

$$= \frac{abcd}{10000} + \frac{ef/99}{10000}$$

Normalize above with **GCD** (Euclid's algorithm)

Use long's and **beware of overflow!**

# Bad Scientist

---

## Graph

- Node for each theory, edge for each contradiction

You may recognize the Maximum Independent Set problem

- State of the art is close to  $O^*(1.3^n)$  but probably infeasible for contest

Dual to **Minimum Vertex Cover** which is **fixed parameter tractable**:  $O^*(2^k)$

- So feasible since  $k$  is low

Multiple **branching** strategies possible, for example:

- Recursively visit all edges
  - If one of the nodes is already excluded, continue with next edge
  - Otherwise: branch
- Stop after all edges have been visited or recursion depth exceeds  $k$

$O(2^k m)$

- Can even be improved to  $O^*(1.3^k)$  but for this contest that was not necessary

---

---

correct

run-error

timelimit

wrong-answer

# Islands

---

First, find minimum distance between each pair of islands

- Shortest distance is always between a vertex and an edge
- For each pair of vertex and edge, calculate line-to-point distance

Use your favorite **shortest path** algorithm to find the final route

$O(n^2 m^2)$

correct run-error timelimit wrong-answer

# Extreme Shopping

Sort shops on price per item

## Dynamic programming

- State: (shop index, number of items to buy)

At each shop, if you decide to buy items there, it is best to buy as many as you can

$f(i, j)$  = best price considering only shop 1 through  $i$ , buying  $j$  items

$$f(i, 0) = 0$$

$$f(0, j) = \infty$$

$$f(i, j) = \min(f(i - 1, j), b \cdot p_i + o_i + f(i - 1, j - b))$$

$$\text{where } b = \min(s_i, j)$$

$O(nm)$

---

---

correct

run-error

timelimit

wrong-answer

# Digital Transmission

---

Try to put in as many ones as possible, while still keeping the string run-length limited

One more time, but with as few ones as possible

This gives an upper bound and a lower bound on the number of ones, it can be proven that everything in between the bounds can also be constructed

$O(n)$

# Gunslinger

---

Check if possible:

- Compute **convex hull** of all Daltons
- Possible iff Luke and Escape hatch are outside or on the hull

If possible, there are 2 options:

- Direct line between Luke and hatch doesn't intersect hull
- Otherwise, walk via the hull (to implement this, take the hull of all points including Luke and hatch)

$O(n \log n)$

- But  $O(n^2)$  was also accepted

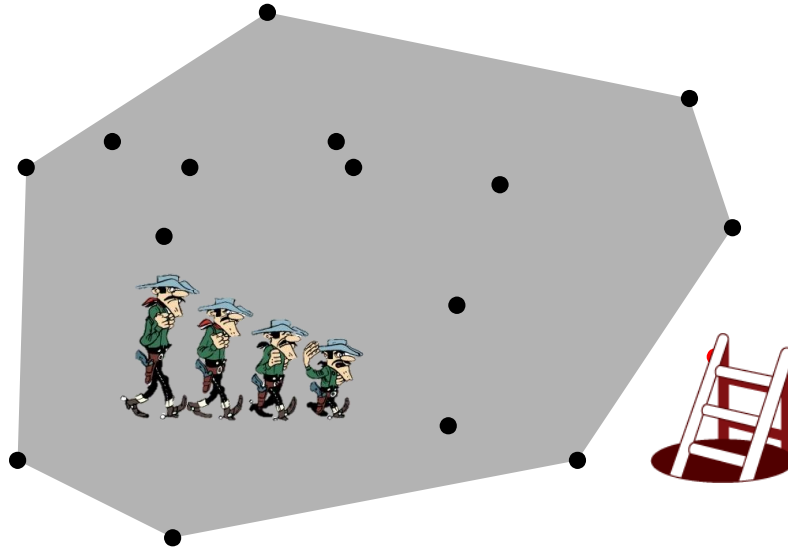

correct run-error timelimit wrong-answer
